When creating a survey there is a subtle sense of cooperation between two parties: the survey maker and the survey taker. The former makes the rules and the latter decides when to follow them.

The survey maker wants  
information of its demographic

The survey taker wants their  
information to be private  
and secure

Binary RRT (Randomized Response Techniques) effectively randomly changes the yes/no response from a survey taker unbeknownst to the survey maker. This is usually accomplished through a secondary question which occurs at a random rate of  $1-p$ . With the sensitive question (with a true population occurrence at  $\pi_x$ ) at probability  $p$ .

Sensitive Question:

"Have you purposefully neglected care of your parents?"

Alternate Questions:

"Have you never purposefully neglected care of your parents?"

(Warner's Model)

-OR-

"Is your favorite color blue?"

(Greenberg's Model)

# Indirect Question Model [Warner, 1965]

Now imagine yourself as a participant of a survey. Of course there is some level of privacy in which you would answer truthfully for. If the survey maker does not provide this level of privacy (i.e. a value of  $p$  which is too high) you may still find lying is a viable option and as such RRT will usually never have 100% compliance to instructions.

For example given the following with Greenberg's Model parameters:

$$n = 500, \pi_x = .3, \pi_y = .1$$

$p$	$1-p$	$A$	$\hat{\pi}$	$\widehat{MSE}$	$MSE$
.5	.5	1	.29984	.00128	.00128
.5	.5	.9	.27023	.00209	.00218
.5	.5	.8	.23967	.00478	.00488
.7	.3	1	.30023	.00076	.00075
.7	.3	.9	.27006	.00160	.00165
.7	.3	.8	.24035	.00424	.00435

Proposed by [Young et al., 2019] a primer question was proposed to ask the participant "Do you trust this model" (i.e. would you respond truthfully). As this information itself is sensitive it must also be placed in a RRT survey format.

This extra information gives us a value of  $A$ . The proportion of participants who respond truthfully to the instructions of RRT and would not lie with the current parameters in RRT.

**Efficiency:** The ability for the researcher to get close to the true proportion of  $\pi_x$ , measured by MSE

**Privacy:** The sense of security in the participant of the survey. This have many diverse measures.

Overall, Greenberg's model tends to have better efficiency measures while Warner's model tends to have better privacy.

So it seems that a "mixture" of the two models would be able to strike a balance in these two categories.

$p_0$  = The proportion of the direct question used in a Greenberg model to estimate truthfulness.

$\pi_{y0}$  = The proportion of people who would answer yes to the unrelated question in the Greenberg model to estimate A  
 $p$ ,  $q$ ,  $\pi_x$ ,  $\pi_y$ , A are all the same from the introduction of the mixture model

Question 1: (With Greenberg) Do you trust the model?

$$P_{y0} = P_0(\text{Yes}) = p_0 A + (1 - p_0)\pi_{y0}$$

$$\hat{A} = \frac{\hat{P}_{y0} - (1 - p_0)\pi_{y0}}{p_0} \quad (1)$$

$$E(\hat{A}) = A, \quad \text{Var}(\hat{A}) = \frac{P_{y0}(1 - P_{y0})}{(n - 1)p_0^2} \quad (2)$$

Question 2: (With Mixture Model) Do you have sensitive trait?

$$P_y = P(\text{Yes}) = \pi_x A(p - q) + q + (1 - p - q)\pi_y$$

$$\hat{\pi}_x = \frac{\hat{P}_y - q - (1 - p - q)\pi_y}{\hat{A}(p - q)}; p \neq q \quad (3)$$

$$E(\hat{P}_y) = P_y = \pi_x A(p - q) + q + (1 - p - q)\pi_y, \text{Var}(\hat{P}_y) = \frac{P_y(1 - P_y)}{(n - 1)(p - q)^2}; p \neq q \quad (4)$$

Then using first order Taylor's approximation,  $\hat{\pi}_x$  can be approximated by:

$$\hat{\pi}_x \approx \frac{P_y - q - (1 - p - q)\pi_y}{A(p - q)} - (\hat{A} - A) \left[ \frac{P_y - q - (1 - p - q)\pi_y}{A^2(p - q)} \right] + (\hat{P}_y - P_y) \left[ \frac{1}{A(p - q)} \right] \quad (5)$$

[where  $p \neq q$ ]

It is easy to see from (5) that,

$$E(\hat{\pi}_x) = \pi_x$$

$$\text{Var}(\hat{\pi}_x) = \left[ \frac{P_y - q - (1 - p - q)\pi_y}{A^2(p - q)} \right]^2 \text{Var}(\hat{A}) + \left[ \frac{1}{A(p - q)} \right]^2 \text{Var}(\hat{P}_y)$$

$\text{Var}(\hat{A})$  is given in (2) and  $\text{Var}(\hat{P}_y)$  is given in (4)

[Lanke, 1976], in previous work, described privacy loss as,

$$\delta = \text{Max}(\eta_1, \eta_2)$$

$$\eta_1 = \text{Pr}(S|Y) = \frac{pA\pi_x + (1 - p - q)\pi_x\pi_y + q\pi_x(1 - A)}{\pi_x A(p - q) + q + (1 - p - q)\pi_y}$$

$$\eta_2 = \text{Pr}(S|N) = \frac{qA\pi_x + (1 - p - q)(1 - \pi_y)\pi_x + p\pi_x(1 - A)}{1 - [\pi_x A(p - q) + q + (1 - p - q)\pi_y]}$$

**Result:**  $\delta$  is at its minimum if  $p = q$ ,  $\min(\delta) = \pi_x$

**Proof:**

$\implies$  Let  $p = q$ , then

$$P(S|Y) = \frac{\pi_x[pA + (1-p-q)\pi_y + q(1-A)]}{\pi_x A(p-q) + q + (1-p-q)\pi_x} = \pi_x$$

$$P(S|N) = \frac{\pi_x[qA + (1-p-q)(1-\pi_y) + p(1-A)]}{\pi_x A(q-p) + p + (1-p-q)(1-\pi_y)} = \pi_x$$

Hence  $\delta = \pi_x$ , when  $p = q$

Now Assume,

$$\exists p \text{ and } \exists q \text{ st. } P(S|Y) < \pi_x \text{ and } P(S|N) < \pi_x$$

$$\implies \frac{P(S \cap Y)}{P(Y)} < \pi_x \text{ and } \frac{P(S \cap N)}{P(N)} < \pi_x$$

$$\implies P(S \cap Y) < \pi_x P(Y) \text{ and } P(S \cap N) < \pi_x P(N)$$

$$\implies P(S \cap Y) + P(S \cap N) < \pi_x P(Y) + \pi_x P(N)$$

$$\implies P(S) < \pi_x$$

This creates a contradiction proving that  
 $\text{Min } \delta = \pi_x$  and it is attained at  $p = q$

Given a choice of  $p$  there is a corresponding  $q$  such that our unified measure is maximized. Meaning we have a good mix of privacy and efficiency. the choice of  $p$  is still vital as it is now the main factor for how one avoids large amounts of untruthfulness in models.

Once we choose a  $p$  one can begin to find the most optimal mixture of  $(1-p)$  between  $q$  and  $1-p-q$  for a model with respect to  $\mathbb{M}$  with a prior guess of what  $\pi_x$  would be.

Of course there are fluctuations where each model is optimized due to  $\pi_x$ ,  $\pi_y$ , and if one accounts for A or not, but in General:

- for most values,  $\mathbb{M}$  is significantly higher if one accounts for A
- if  $p \in [0, .15] \cup [.4, .85]$ , then the mixture model has a higher  $\mathbb{M}$ , making it the best choice of a model for a significant portion of  $p$ .
- the  $p = 0$  branch results in the highest  $\mathbb{M}$  overall, indicating that using only indirect question and unrelated question might be the new standard for RRT
- Of course these results vary with the parameters of the models but the mixed model does have its place as it balances out efficiency and privacy well
